

INDEX – XML

S.N.	TITLE	DATE OF SUBMISSION	SIGNATURE
XML Basics and Structure			
61.	Create a simple XML document that represent a list of students, where each student has the following details: name, roll number, department, and year. Display the XML tree structure.		
62.	Create an XML file for a book catalog. Each book should contain title, author, publisher, price, and ISBN as elements or attributes. Ensure proper syntax and nesting.		
63.	Demonstrate the use of XML attributes vs elements using a real-world example such as a product catalog or employee list. Explain the pros and cons.		
DTD (Document Type Definition)			
64.	Create an XML document for employee data and write an external DTD to validate it. Include elements like employee, name, id, department, and salary.		
65.	Modify the above XML and DTD to allow multiple phone numbers and optional email addresses for each employee.		
XSD (XML Schema Definition)			
66.	Design an XML document for an outline order containing customer details, order, ID, a list of products (with name, quantity, and price), and total amount. Then write an XSD schema to validate the XML with appropriate data types and constrains (e.g., integers, strings, decimals).		
67.	Write an XML Schema (XSD) to validate a student record system, where students have complex types like address (with sub-elements: street, city, zip code), and simple types like name and grade.		
Namespace			
68.	Create an XML document that uses two different namespaces — one for employee personal details and one for job-related information. Display how to differentiate the elements using prefixes.
